Package 'lgpr'

January 25, 2020

Title Longitudinal Gaussian Process Regression

Version 0.32.0

Description Implements interpretable nonparametric analysis and
covariate selection for longitudinal data using additive
Gaussian process regression. Includes specialized non-stationary disease
effect modeling features for biomedical studies. Bayesian inference for
model parameters is performed using Stan.

`lgpr-package`	*The 'lgpr' package.*

Description

Longitudinal Gaussian Process regression. The package features

- Additive Gaussian process modeling of longitudinal data
- Posterior inference of the model (hyper)parameters using Stan
- Computation of covariate relevances
- Specialized modeling of a non-stationary disease effect
- Functions for visualizing longitudinal data, posterior samples and model predictions
- Gaussian, Poisson, binomial or negative binomial observation models

Basic usage

- See the main function `lgp` for creating and fitting additive longitudinal GP models.
- See tutorials at https://jtimonen.github.io/lgpr-usage/index.html

Citation

An interpretable probabilistic machine learning method for heterogeneous longitudinal studies. Juho Timonen, Henrik Mannerstrom, Aki Vehtari and Harri Lahdesmaki, 2019. https://arxiv.org/abs/1912.03549

---

add_categorical_covariate

Easily add a categorical covariate to a data frame

Description

Easily add a categorical covariate to a data frame

Usage

```
add_categorical_covariate(data, x, id_var = "id")
```

Arguments

data	the original data frame
x	A named vector containing the category for each individual. The names should specify the individual id.
id_var	name of the id variable in data

Value

A data frame with one column added. The new column will have same name as the variable passed as input x.

---

add_diseaseAges   *Create the disease-related age covariate vector based on the disease initiation times and add it to the data frame*

Description

Create the disease-related age covariate vector based on the disease initiation times and add it to the data frame

Usage

```
add_diseaseAges(data, t_init, id_var = "id", time_var = "age")
```

Arguments

data	the original data frame
t_init	A named vector containing the observed initiation or onset time for each individual. The names, i.e. names(t_init), should specify the individual id.
id_var	name of the id variable in data
time_var	name of the time variable in data

Value

A data frame with one column added. The new column will be called 'diseaseAge'. For controls, the value of diseaseAge will be set to NaN.

---

add_test_caseIDs *Add case IDs to test data frame*

Description

Add case IDs to test data frame

Usage

```
add_test_caseIDs(X_test, X_data)
```

Arguments

X_test   test data frame

X_data   data frame

Value

Updated X_test data frame.

---

adjusted_Chat *Create the GP mean input for* lgp*, so that it accounts for normalization between data points in the Poisson or NB observation model*

Description

Create the GP mean input for lgp, so that it accounts for normalization between data points in the Poisson or NB observation model

Usage

```
adjusted_Chat(y, norm_factors)
```

Arguments

y   response variable, vector of length n

norm_factors   normalization factors, vector of length n

Value

a vector of length n, which can be used as the C_hat input to the lgp function

---

affected   *Select the affected individuals*

Description

Select the affected individuals

Usage

```
affected(object, medians.return = FALSE, threshold = 0.5)
```

Arguments

object	An object of class `lgpfit`.
medians.return	Should the medians of beta parameters also be returned?
threshold	A value that the median of beta has to exceed

Value

A binary vector indicating the individuals for which the disease effect is inferred to exist.

---

assess_convergence   *Assess convergence of the chains*

Description

Assess convergence of the chains

Usage

```
assess_convergence(fit, skip_F_gen = TRUE)
```

Arguments

fit	An (incomplete) object of class `lgpfit`.
skip_F_gen	Should F_mean, F_var etc. be ignored

Value

A data frame with columns c("Rhat","Bulk_ESS","Tail_ESS").

---

average_predictions *Average predictions over samples*

Description

Average predictions over samples

Usage

```
average_predictions(LIST)
```

Arguments

LIST   a list over samples

Value

a list

---

check_data *Validate the 'data' input to* lgp *and resolve covariate types*

Description

Validate the 'data' input to lgp and resolve covariate types

Usage

```
check_data(data, varInfo, verbose)
```

Arguments

data   the data frame that was passed to lgp

varInfo   variable type info

verbose   can this print some info?

Value

a list

---

check_formula   *Validate the formula of* lgp

Description

Checks if the input 'formula' to lgp_model are valid with the given data

Usage

```
check_formula(formula, data)
```

Arguments

formula	the formula that was passed to lgp_model
data	the data frame that was passed to lgp_model

Value

nothing

---

check_hyperparameter_names
                    An error message for wrong hyperparameter naming

---

Description

An error message for wrong hyperparameter naming

Usage

```
check_hyperparameter_names(dist, correct)
```

Arguments

dist	the distribution
correct	the allowed hyperparameter names

Value

nothing

check_varInfo *Check that variable types make sense*

Description

Check that variable types make sense

Usage

```
check_varInfo(varInfo)
```

Arguments

varInfo   a named list

Value

nothing

component_index_to_covariate_index
Component index to covariate index

Description

Component index to covariate index

Usage

```
component_index_to_covariate_index(D, idx)
```

Arguments

D   integer vector of length 6

idx   integer

Value

an integer

component_index_to_type

Component index to component type

Description

Component index to component type

Usage

```
component_index_to_type(D, idx)
```

Arguments

D	integer vector of length 6
idx	integer

Value

an integer

compute_kernel_matrices

Evaluate kernel matrices for each component

Description

Used by compute_predictions.

Usage

```
compute_kernel_matrices(X1, X2, kernel_info)
```

Arguments

X1	Covariate matrix of size n1 x sum(D).
X2	Covariate matrix of size n2 x sum(D).
kernel_info	A list of parameters and other kernel info.

Value

An array of size n1 x n2 x sum(D).

---

compute_lppd *Compute log-posterior predictive density at test points*

Description

Compute log-posterior predictive density at test points

Usage

```
compute_lppd(PRED, y_test)
```

Arguments

PRED	predictions
y_test	values of the response variable at the test points

Value

a matrix with size `n_samples` x `n_data`

---

compute_noise_level *Determine noise level*

Description

Determine noise level

Usage

```
compute_noise_level(pars, model, noise_method)
```

Arguments

pars	A data frame representing one parameter sample, i.e one row of as.data.frame(stanfit), where stanfit is an object of class stanfit
model	An object of class lgpmodel
noise_method	Noise level estimation method.

Value

a value between 0 and 1

compute_predicted_components
                             Compute component-wise predictions at test points

Description

Used by [compute_predictions](#).

Usage

```
compute_predicted_components(KK, KKs, KKss, y_data, sigma_n, DELTA)
```

Arguments

KK	Kernel matrices data vs. data.
KKs	Kernel matrices test vs. data.
KKss	Kernel matrices test vs. test.
y_data	Response variable.
sigma_n	Noise standard deviation parameter.
DELTA	Diagonal jitter that ensures pos. def. kernel.

Value

A list containing predicted means and variances.

compute_predictions   *Compute component-wise predictions at test points*

Description

Used by [lgp_predict](#).

Usage

```
compute_predictions(
  X_data,
  y_data,
  X_test,
  params,
  D,
  info,
  cnames,
  TSCL,
  handle_extra = "warning"
)
```

Arguments

X_data	Covariate matrix (data points).
y_data	Response variable (data points).
X_test	Covariate matrix (test points).
params	Kernel function and other hyperparameters
D	a vector of length 6
info	other model info
cnames	Names of the model components.
TSCL	time scaling function and its inverse
handle_extra	What to do if test data contains individuals that are not in the training data? Must be 'silent', 'warning' or 'error'.

Value

A list.

---

compute_relevances	*Compute component relevances and estimate amount of noise (one MCMC sample)*

Description

Compute component relevances and estimate amount of noise (one MCMC sample)

Usage

```
compute_relevances(pars, model, method, noise_method)
```

Arguments

pars	A data frame representing one parameter sample, i.e one row of as.data.frame(stanfit), where stanfit is an object of class stanfit
model	An object of class lgpmodel
method	Relevance determination method. Must be either "f_mean" or "alpha".
noise_method	Noise level estimation method.

Value

a matrix of size 1 x n_components + 1

---

compute_relevances_alpha

The alpha relevance determination method

Description

The alpha relevance determination method

Usage

```
compute_relevances_alpha(pars, model)
```

Arguments

pars   A data frame representing one parameter sample, i.e one row of as.data.frame(stanfit),
              where stanfit is an object of class stanfit

model   An object of class lgpmodel

Value

a vector of length n_components

---

compute_relevances_fmean

The f_mean relevance determination method

Description

The f_mean relevance determination method

Usage

```
compute_relevances_fmean(pars, model)
```

Arguments

pars   A data frame representing one parameter sample, i.e one row of as.data.frame(stanfit),
              where stanfit is an object of class stanfit

model   An object of class lgpmodel

Value

a vector of length n_components

create_covariates_stan

Create the covariate matrix that is given to stan

Description

Create the covariate matrix that is given to stan

Usage

```
create_covariates_stan(data, varInfo, types, formula, verbose)
```

Arguments

data	the data frame that was passed to lgp
varInfo	original variable type info
types	the types returned by check_data
formula	the model formula
verbose	can this print some info?

Value

a list

create_data_plot_df   *Create a plotting data frame for ggplot*

Description

A helper function for plot_data.

Usage

```
create_data_plot_df(data, hl_1, hl_2, hl_cont)
```

Arguments

data	a data frame
hl_1	highlighting by color
hl_2	highlighting by linestyle
hl_cont	highlighting continuous

Value

an extended data frame

---

create_example_fit   *Create an example fit object*

Description

Create an example fit object

Usage

```
create_example_fit(N = 4, t = 10 * c(1, 2, 3, 4, 5), iter = 100, chains = 1)
```

Arguments

N	number of individuals
t	time points
iter	number of iterations
chains	number of chains

Value

an object of class `lgpfit`

---

create_F   *Simulate latent function components for longitudinal data analysis*

Description

Simulate latent function components for longitudinal data analysis

Usage

```
create_F(
  X,
  covariates,
  relevances,
  lengthscales,
  X_affected,
  dis_fun,
  bin_kernel,
  steepness,
  vm_params,
  force_zeromean
)
```

Arguments

X	input data matrix (generated by [create_X](#))
covariates	Integer vector that defines the types of covariates (other than id and age). Different integers correspond to the following covariate types:

- 0 = disease-related age
- 1 = other continuous covariate
- 2 = a categorical covariate that interacts with age
- 3 = a categorical covariate that acts as a group offset
- 4 = a categorical covariate that that acts as a group offset AND is restricted to have value 0 for controls and 1 for cases

relevances	Relative relevance of each component. Must have be a vector so that `length(relevances) = 2 + length(covariates)`. First two values define the relevance of the infividual-specific age and shared age component, respectively.
lengthscales	A vector so that `length(lengthscales) = 2 + sum(covariates %in% c(0,1,2))`.
X_affected	which individuals are affected by the disease
dis_fun	A function or a string that defines the disease effect. If this is a function, that function is used to generate the effect. If dis_fun is "gp_vm" or "gp_ns", the disease component is drawn from a nonstationary GP prior (vm is the variance masked version of it).
bin_kernel	Should the binary kernel be used for categorical covariates? If this is TRUE, the effect will exist only for group 1.
steepness	Steepness of the input warping function. This is only used if the disease component is in the model.
vm_params	Parameters of the variance mask function. This is only needed if useMaskedVarianceKernel = TRUE.
force_zeromean	Should each component (excluding the disease age component) be forced to have a zero mean?

Value

a data frame FFF where one column corresponds to one additive data component

---

create_predictions_plot_df1

Create a plotting data frame for ggplot

Description

A helper function for `plot_predictions`.

Usage

```
create_predictions_plot_df1(fit, scale_f = TRUE, n_sds)
```

Arguments

`fit`	An object of class `lgpfit`.
`scale_f`	Should the predictions be scaled back to the original data scale?
`n_sds`	number of standard deviations for the uncertainty band width

Value

a data frame

`create_predictions_plot_df2`
                Create a plotting data frame for ggplot

Description

A helper function for `plot_predictions`.

Usage

```
create_predictions_plot_df2(model, PRED, scale_f = TRUE, mode, n_sds)
```

Arguments

`model`	An object of class `lgpmodel`.
`PRED`	Predictions computed using `lgp_predict`.
`scale_f`	Should the predictions be scaled back to the original data scale?
`mode`	mode
`n_sds`	number of standard deviations for the uncertainty band width

Value

a data frame

`create_simdata_plot_df`
                Create a plotting data frame for ggplot

Description

A helper function for `plot_simdata_by_component`.

Usage

```
create_simdata_plot_df(simData)
```

Arguments

`simData`	An object created using `simulate_data`.

Value

a data frame

---

create_stan_input | *Create input for Stan*

Description

Parses the formula and data input to [lgp_model](#). Also performs many input checks.

Usage

```
create_stan_input(
  formula,
  data,
  prior,
  likelihood,
  varInfo,
  standardize,
  uncertain_effect_time,
  equal_effect,
  C_hat,
  DELTA,
  sample_F,
  verbose,
  variance_mask,
  N_trials,
  skip_gen_quant
)
```

Arguments

formula
A formula of the form y ~ x1 + x2 + x3 defining the response variable y and covariates xi. The formula must contain exatly one tilde (~), with response variable on the left-hand side and covariates on the right-hand side. Covariates should be separated by a plus (+) sign. All variables that appear in the formula must exist as columns of data. Note that effects of categorical covariates are by default defined as interactions with time_variable. If you wish to change this, see the argument offset_vars. The subject identifier variable cannot currently be included in offset_vars. If you wish to model the effect of id_variable as a constant offset, you can create another covariate with the same values and use it in your formula and offset_vars instead.

data
A data frame containing the variables given in formula as columns.

prior
A named list, defining the prior distribution of model (hyper)parameters. It is recommended to first create this using the function [prior_default](#), and then possibly modify it.

likelihood
Determines the observation model. Must be either "Gaussian" (default), "Poisson", "NB" (negative binomial) or "binomial". To use Bernoulli likelihood, use likelihood="binomial" and set N_trials as a vector of ones.

varInfo	Variable type info.
standardize	Should the response variable be standardized?
uncertain_effect_time	
	Do we wish to model uncertainty in the disease effect time?
equal_effect	Is the disease effect assumed to be equally strong for all diseased individuals?
C_hat	The GP mean. Must be a vector of length dim(data)[1], or a real number defining a constant GP mean. If NULL, this is set to

- C_hat = 0, if likelihood is "Gaussian", because with Gaussian likelihood the response variable is by default centered to have zero mean.
- C_hat = log(mean(y)) if likelihood is "Poisson" or "NB",
- C_hat = log(p/(1-p)), where p = mean(y/N_trials) if likelihood is "binomial",

where y denotes the response variable. You can modify this vector to account for normalization between data points. With Gaussian likelihood though, do not modify this argument, normalize the data beforehand instead.

DELTA	the amount of added jitter to ensure positive definiteness of the kernel
sample_F	Determines if the function values are be sampled (must be TRUE if likelihood is not "Gaussian").
verbose	Should more verbose output be printed?
variance_mask	Should a variance mask be used to force disease component variance to zero before disease onset?
N_trials	This argument (number of trials) is only needed when likelihood is binomial. Must have length one or equal to number of data points. Setting N_trials=1 corresponds to Bernoulli observation model.
skip_gen_quant	If this is true, the generated quantities block of Stan is skipped.

Value

A list containing the data to be given to rstan::sampling, some info about preprocessing and all the information about scaling the inputs and response, and updated variable type info.

---

create_test_points   *Create a matrix of test points*

Description

Create a matrix of test points

Usage

```
create_test_points(object, t_test)
```

Arguments

object	An object of class lgpmodel or lgpfit
t_test	Test time points (will be same for each individual).

Value

A data frame.

---

create_X   *Simulate an input data frame X*

Description

Simulate an input data frame X

Usage

```
create_X(
  N,
  covariates,
  names,
  n_categs,
  t_data,
  t_jitter,
  t_effect_range,
  continuous_info,
  verbose
)
```

Arguments

N	Number of individuals.
covariates	Integer vector that defines the types of covariates (other than id and age). If not given, only the id and age covariates are created. Different integers correspond to the following covariate types:

     • 0 = disease-related age

     • 1 = other continuous covariate

     • 2 = a categorical covariate that interacts with age

     • 3 = a categorical covariate that acts as a group offset

     • 4 = a categorical covariate that that acts as a group offset AND is restricted to have value 0 for controls and 1 for cases

names	Covariate names.
n_categs	An integer vector defining the number of categories for each categorical covariate, so that `length(n_categs)` equals to the number of 2's and 3's in the `covariates` vector.
t_data	Measurement times.
t_jitter	Standard deviation of the jitter added to the given measurement times.
t_effect_range	Time interval from which the disease effect times are sampled uniformly. Alternatively, This can any function that returns the (possibly randomly generated) real disease effect time for one individual.
continuous_info	

        Info for generating continuous covariates. Must be a list containing fields `lambda` and `mu`, which have length 3. The continuous covariates are generated so that x `<-sin(a*t + b) + c`, where

     • `t <-seq(0, 2*pi, length.out = k)`

     • `a <-mu[1] + lambda[1]*stats::runif(1)`

- b <-mu[2] + lambda[2]*stats::runif(1)
- c <-mu[3] + lambda[3]*stats::runif(1)

verbose   verbosity mode

Value

list(X,onsets,par_cont)

---

create_X_star   *Create X_star*

Description

Create X_star

Usage

create_X_star(X, D, t_test, SCL, X_notnan)

Arguments

X	covariate matrix
D	covariate type information
t_test	Test time points (will be same for each individual).
SCL	time scaling function and its inverse
X_notnan	indicates where X_diseaseAge is not NaN

Value

A data frame.

---

create_y   *Generate noisy observations*

Description

Generate noisy observations

Usage

create_y(noise_type, f, snr, phi, N_trials)

Arguments

noise_type	Either "Gaussian", "Poisson", NB" (negative binomial) or "binomial".
f	The underlying signal.
snr	The desired signal-to-noise ratio. This argument is valid only with noise_type = "Gaussian".
phi	The dispersion parameter for negative binomial data. The variance is $g + g^2/phi$.
N_trials	The number of trials parameter for binomial data.

Value

A list out, where

- `out$g` is f mapped through an inverse link function and
- `out$y` is the noisy response variable.

---

disease_effect   *Draw disease component from a parameteric form*

Description

Draw disease component from a parameteric form

Usage

```
disease_effect(X_id, X_disAge, dis_fun)
```

Arguments

X_id	the id covariate
X_disAge	the diseaseAge covariate
dis_fun	the disease age effect function

Value

a vector

---

drawCategorical   *Indepedently draw categorical variables for each individual*

Description

Indepedently draw categorical variables for each individual

Usage

```
drawCategorical(N, k, v)
```

Arguments

N	number of individuals
k	number of timepoints
v	vector of numbers of different categories

Value

a matrix of size N x D, where `D <-length(v)`

---

drawContinuous   *Indepedently draw continuous variables for each individual*

Description

Indepedently draw continuous variables for each individual

Usage

```
drawContinuous(N, k, D, mu, lambda)
```

Arguments

N	number of individuals
k	number of timepoints
D	number of variables
mu	a vector of length 3
lambda	a vector of length 3

Value

a matrix of size N x D

---

drawLatentComponents   *Draw realizations of multivariate normals*

Description

Draw realizations of multivariate normals

Usage

```
drawLatentComponents(KK)
```

Arguments

KK	3D matrix where KK[,,j] is the jth kernel matrix

Value

a matrix FFF

---

drawMeasurementTimes *Draw the age covariate*

Description

Draw the age covariate

Usage

```
drawMeasurementTimes(N, t_data, t_jitter)
```

Arguments

N	number of individuals
t_data	a vector of length k
t_jitter	Standard deviation of the jitter added to the given measurement times.

Value

a vector of length N*k

---

example_call *Returns a valid example call of the* lgp *function witi valid data input*

Description

Returns a valid example call of the lgp function witi valid data input

Usage

```
example_call()
```

Value

a string

---

extract_t_effect_samples
Extract samples of T_effect

Description

Extract samples of T_effect

Usage

```
extract_t_effect_samples(fit)
```

Arguments

fit   an object of class `lgpfit`

Value

a matrix

---

full_model   *Create a full model with all covariates included*

Description

Create a full model with all covariates included

Usage

```
full_model(data, ...)
```

Arguments

data   a data frame

...   additional parameters to `lgp_model`

Value

a ggplot object

full_model_formula   *Get formula of a full model with all covariates included*

Description

Get formula of a full model with all covariates included

Usage

```
full_model_formula(data)
```

Arguments

data   a data frame, where the response variable is the last column

Value

a formula

get_case_ids   *Get case ids in original data*

Description

Get case ids in original data

Usage

```
get_case_ids(fit)
```

Arguments

fit   an object of class lgpfit

Value

a character vector

---

get_case_row_mappings *Create case ID to rows and back mappings*

Description

Create mappings

- from case ID to data rows (caseID_to_rows, caseID_nrows)
- from row number to case ID (row_to_caseID)

Usage

```
get_case_row_mappings(X_notnan, X_id, only_R2C = FALSE)
```

Arguments

X_notnan	binary vector indicating if diseaseAge is available for that measurement
X_id	the id covariate in X
only_R2C	should this return only the rows-to-caseID mapping

Value

a list

---

get_diseased_info *Get some variables related to diseased individuals*

Description

Get some variables related to diseased individuals

Usage

```
get_diseased_info(D, X, X_notnan, uncertain_effect_time, equal_effect, TSCL)
```

Arguments

D	an integer vector of length 6
X	the design matrix
X_notnan	a binary vector of length n
uncertain_effect_time	
	Boolean value
equal_effect	Boolean value
TSCL	time scaling function and its inverse

Value

a list

get_function_components_from_df
Get values of function components at data points, for one MCMC sample-ple

Description

Get values of function components at data points, for one MCMC sample

Usage

```
get_function_components_from_df(pars, model)
```

Arguments

pars	A data frame representing one parameter sample, i.e one row of as.data.frame(stanfit), where stanfit is an object of class stanfit
model	An object of class lgpmodel

Value

A matrix of size n_data x n_components+2

get_function_components_from_df_all
Get values of function components at data points

Description

Get values of function components at data points

Usage

```
get_function_components_from_df_all(df, model)
```

Arguments

df	A stanfit object as data frame, obtained as as.data.frame(stanfit)
model	An object of class lgpmodel

Value

An array of size n_samples x n_data x n_components+2

---

get_g_from_f   *Get signal on data scale from process f*

Description

Get signal on data scale from process f

Usage

```
get_g_from_f(f, model)
```

Arguments

f   A vector

model   an object of class `lgpmodel`

Value

A vector g

---

get_model_dims   *Get some dimension variables that the Stan model needs as input*

Description

Get some dimension variables that the Stan model needs as input

Usage

```
get_model_dims(X, D)
```

Arguments

X   the design matrix

D   a vector of length 6

Value

a list

---

get_obs_onset_times   *Extract observed disease onset times from diseaseAge covariate vector*

Description

Extract observed disease onset times from diseaseAge covariate vector

Usage

```
get_obs_onset_times(id, age, disAge)
```

Arguments

id	the id covariate, vector of length n
age	the age covariate, vector of length n
disAge	the observed disease-related age covariate, vector of length n

Value

vector of observed onset times

---

get_onset_info   *Get disease onset info*

Description

This returns

- a vector of observed onsets
- mapping from case ID to average sampling interval before the observed disease onset

Usage

```
get_onset_info(D, X, MAPS, TSCL)
```

Arguments

D	an integer vector of length 6
X	the design matrix
MAPS	mappings created by get_case_row_mappings
TSCL	time scaling function and its inverse

Value

two vectors of length N_cases

get_pkg_description   *Get lgpr version description*

Description

Get lgpr version description

Usage

```
get_pkg_description()
```

Value

package description

get_predicted   *A helper function*

Description

A helper function

Usage

```
get_predicted(fit)
```

Arguments

fit   An (incomplete) object of class lgpfit.

Value

a list

get_prior_params   *Get prior parameters*

Description

Get prior parameters

Usage

```
get_prior_params(dist, add_correct)
```

Arguments

dist   the distribution

add_correct   additional correct parameter names

Value

a hyperparameter vector of length 2

---

get_prior_type *A dictionary from distribution names to integer encoding*

Description

A dictionary from distribution names to integer encoding

Usage

```
get_prior_type(type)
```

Arguments

type   type of the distribution as a string

Value

an integer

---

get_response *Get the (scaled) response variable*

Description

Gets and possibly scales the response variable.

Usage

```
get_response(data, varInfo, standardize, LH)
```

Arguments

data   the data frame given as input to lgp

varInfo   variable type info

standardize   should the response be standardized to unit variance and zero mean

LH   likelihood as integer

Value

a list with the (scaled) response variable

get_runtime   *Get average runtime of a chain*

Description

Get average runtime of a chain

Usage

```
get_runtime(object)
```

Arguments

object   An object of class `lgpfit`.

Value

Average runtimes for warmup and sampling

get_stan_model   *Get main stan model of the package*

Description

Get main stan model of the package

Usage

```
get_stan_model()
```

Value

an object of class stanmodel

get_transform_type   *A dictionary from transform names to integer encoding*

Description

A dictionary from transform names to integer encoding

Usage

```
get_transform_type(type)
```

Arguments

type   Type of the transform as a string. Allowed arguments are "none" or "square". If
                NULL, "none" is used.

Value

an integer (0, 1 or 2)

---

hyperparam_estimate   *Get a posterior estimate of model (hyper)parameters*

Description

Get a posterior estimate of model (hyper)parameters

Usage

```
hyperparam_estimate(object, type = "mean")
```

Arguments

object	An (incomplete) object of class `lgpfit`.
type	Must be "mean", "median", or "map".

Value

a data frame

---

hyperparam_samples   *Get a set of model (hyper)parameter samples*

Description

Get a set of model (hyper)parameter samples

Usage

```
hyperparam_samples(object, samples = NULL)
```

Arguments

object	An (incomplete) object of class `lgpfit`.
samples	Sample indices. If NULL, all samples are taken.

Value

a data frame

---

idx_to_cont_index   *Component index to how manyth continuous covariate it is*

Description

Component index to how manyth continuous covariate it is

Usage

```
idx_to_cont_index(D, idx)
```

Arguments

D   integer vector of length 6

idx   an integer

Value

an integer

---

kernel_beta   *Compute the multiplier matrix K_beta (to eneable heterogeneous disease effect)*

Description

Compute the multiplier matrix K_beta (to eneable heterogeneous disease effect)

Usage

```
kernel_beta(beta, row_to_caseID_1, row_to_caseID_2)
```

Arguments

beta   a row vector of length N_cases

row_to_caseID_1

                mapping from row index to case ID

row_to_caseID_2

                mapping from row index to case ID

Value

a matrix

---

kernel_bin   *Compute a binary kernel matrix*

Description

Compute a binary kernel matrix

Usage

```
kernel_bin(x1, x2 = NULL, alpha = 1, pos_class = 1)
```

Arguments

x1	(integer) vector of length n
x2	(integer) vector of length m
alpha	marginal std (default = 1)
pos_class	the positive class label

Value

A kernel matrix of size n x m

---

kernel_ns   *Compute a nonstationary kernel matrix using input warping*

Description

Compute a nonstationary kernel matrix using input warping

Usage

```
kernel_ns(x1, x2 = NULL, alpha = 1, ell, a, b, c, nan_replace = 0)
```

Arguments

x1	vector of length n
x2	vector of length m
alpha	marginal std (default = 1)
ell	lengthscale in the warped space
a	steepness of the warping function rise
b	location of the effective time window
c	maximum range
nan_replace	the value to use for replacing NaN values

Value

A kernel matrix of size n x m

kernel_se	*Compute a squared exponential kernel matrix*

Description

Compute a squared exponential kernel matrix

Usage

```
kernel_se(x1, x2, alpha = 1, ell = 1)
```

Arguments

x1	vector of length n
x2	vector of length m
alpha	marginal std (default = 1)
ell	lengthscale (default = 1)

Value

A kernel matrix of size n x m

kernel_var_mask	*Compute the variance mask kernel matrix*

Description

Compute the variance mask kernel matrix

Usage

```
kernel_var_mask(disAge1, disAge2, vm_params, stp, nan_replace = 0)
```

Arguments

disAge1	disease-related age covariate vector of length n1
disAge2	disease-related age covariate vector of length n2
vm_params	vector of two mask function parameters
stp	input warping steepness
nan_replace	value to replace nans in disAge vectors

Value

a matrix of size n1 x n2

---

kernel_zerosum   *Compute a zero-sum kernel matrix*

Description

Compute a zero-sum kernel matrix

Usage

```
kernel_zerosum(x1, x2, M, alpha = 1)
```

Arguments

x1	(integer) vector of length n
x2	(integer) vector of length m
M	number of categories
alpha	marginal std (default = 1)

Value

A (binary) kernel matrix of size n x m

---

lgp   *The main function of the 'lgpr' package*

Description

This is a wrapper for both [lgp_model](#) and [lgp_fit](#). It first creates an lgpmodel object and then fits the model, finally returning an lgpfit object. Note that the covariate types are automatically inferred from the given data. If you wish to change these, see the arguments

- id_variable
- time_variable
- disAge_variable
- continuous_vars and
- categorical_vars.

Usage

```
lgp(
  formula,
  data,
  likelihood = "Gaussian",
  prior = prior_default(),
  uncertain_effect_time = FALSE,
  equal_effect = TRUE,
  id_variable = "id",
  time_variable = "age",
```

```
    disAge_variable = NULL,
    continuous_vars = NULL,
    categorical_vars = NULL,
    offset_vars = NULL,
    C_hat = NULL,
    DELTA = 1e-08,
    sample_F = NULL,
    parallel = FALSE,
    skip_postproc = FALSE,
    threshold = 0.95,
    variance_mask = TRUE,
    N_trials = NULL,
    relevance_method = "f_mean",
    verbose = FALSE,
    ...
)
```

Arguments

formula	A formula of the form y ~ x1 + x2 + x3 defining the response variable y and covariates xi. The formula must contain exatly one tilde (~), with response variable on the left-hand side and covariates on the right-hand side. Covariates should be separated by a plus (+) sign. All variables that appear in the formula must exist as columns of data. Note that effects of categorical covariates are by default defined as interactions with time_variable. If you wish to change this, see the argument offset_vars. The subject identifier variable cannot currently be included in offset_vars. If you wish to model the effect of id_variable as a constant offset, you can create another covariate with the same values and use it in your formula and offset_vars instead.
data	A data frame containing the variables given in formula as columns.
likelihood	Determines the observation model. Must be either "Gaussian" (default), "Poisson", "NB" (negative binomial) or "binomial". To use Bernoulli likelihood, use likelihood="binomial" and set N_trials as a vector of ones.
prior	A named list, defining the prior distribution of model (hyper)parameters. It is recommended to first create this using the function prior_default, and then possibly modify it.
uncertain_effect_time	
	Do we wish to model uncertainty in the disease effect time?
equal_effect	Is the disease effect assumed to be equally strong for all diseased individuals?
id_variable	Name of the unique subject identifier variable (default = "id").
time_variable	Name of the time variable (default = "age").
disAge_variable	
	Name of the disease-related age variable. If NULL, this will be chosen to be "diseaseAge", if such covariate is found in the data.
continuous_vars	
	Names of other continuous covariates. If NULL, the remaining covariates that have floating point values are interpreted as continuous.
categorical_vars	
	Names of categorical covariates that interact with the time variable. If NULL (default), the remaining covariates that have integer values are interpreted as categorical.

offset_vars	Names of the categorical covariates that are treated as time-independent group offsets. If NULL (default), no variables are interpreted as such covariates.
C_hat	The GP mean. Must be a vector of length dim(data)[1], or a real number defining a constant GP mean. If NULL, this is set to

- C_hat = 0, if likelihood is "Gaussian", because with Gaussian likelihood the response variable is by default centered to have zero mean.
- C_hat = log(mean(y)) if likelihood is "Poisson" or "NB",
- C_hat = log(p/(1-p)), where p = mean(y/N_trials) if likelihood is "binomial",

where y denotes the response variable. You can modify this vector to account for normalization between data points. With Gaussian likelihood though, do not modify this argument, normalize the data beforehand instead.

DELTA	the amount of added jitter to ensure positive definiteness of the kernel
sample_F	Determines if the function values are be sampled (must be TRUE if likelihood is not "Gaussian").
parallel	Determines if the chain will be run in parallel (default = FALSE). If TRUE, then Stan is run by first defining options(mc.cores = parallel::detectCores()).
skip_postproc	In this mode the postprocessing after running Stan is skipped.
threshold	Component selection threshold for relevance sum.
variance_mask	Should a variance mask be used to force disease component variance to zero before disease onset?
N_trials	This argument (number of trials) is only needed when likelihood is binomial. Must have length one or equal to number of data points. Setting N_trials=1 corresponds to Bernoulli observation model.
relevance_method	
	Component relevance determination method. Must be either "f_mean" or "alpha".
verbose	Should more verbose output be printed?
...	Optional arguments passed to rstan::sampling, for example iter, chains or control. See [sampling](#) for the possible arguments.

Value

An object of class lgpfit.

---

lgpfit-class	*An S4 class to represent the output of the* lgp_fit *function*

Description

An S4 class to represent the output of the lgp_fit function

Slots

stan_fit The stanfit object returned by rstan::sampling.

model The lgpmodel object returned by lgp_model.

relevances Inferred component relevances.

selection Component selection info.

pkg_version Package version number.

diagnostics A data frame with columns c("Rhat","Bulk_ESS","Tail_ESS").

lgpmodel-class   *An S4 class to represent an lgp model*

Description

An S4 class to represent an lgp model

Slots

data The original unmodified data frame.

stan_dat The data to be given as input to rstan::sampling.

scalings Preprocessing scaling functions and their inverse operations.

info Model info.

lgp_component_names   *Get names of model components*

Description

Get names of model components

Usage

```
lgp_component_names(stan_dat)
```

Arguments

stan_dat   The data that was passed to rstan::sampling

Value

names of model components

lgp_covariate_names   *Get names of model covariates*

Description

Get names of model covariates

Usage

```
lgp_covariate_names(stan_dat)
```

Arguments

stan_dat   The data that was passed to rstan::sampling

Value

names of model components

---

lgp_fit   *Fit an lgp model*

Description

Samples the posterior of an additive Gaussian process regression model using [rstan](#).

Usage

```
lgp_fit(
  model,
  threshold = 0.95,
  parallel = FALSE,
  skip_postproc = FALSE,
  relevance_method = "f_mean",
  verbose = FALSE,
  ...
)
```

Arguments

model	An object of class lgpmodel.
threshold	Component selection threshold for relevance sum.
parallel	Determines if the chain will be run in parallel (default = FALSE). If TRUE, then Stan is run by first defining options(mc.cores = parallel::detectCores()).
skip_postproc	In this mode the postprocessing after running Stan is skipped.
relevance_method	
	Component relevance determination method. Must be either "f_mean" or "alpha".
verbose	should some output be printed?
...	Optional arguments passed to rstan::sampling, for example iter, chains or control. See [sampling](#) for the possible arguments.

Value

An object of class lgpfit.

See Also

For the possible additional arguments, see [sampling](#). For creating the lgpmodel input, see [lgp_model](#).

---

lgp_model   *Create an lgp model*

Description

Creates an object of class `lgpmodel`

Usage

```
lgp_model(
  formula,
  data,
  likelihood = "Gaussian",
  prior = prior_default(),
  uncertain_effect_time = FALSE,
  equal_effect = TRUE,
  C_hat = NULL,
  DELTA = 1e-08,
  sample_F = NULL,
  id_variable = "id",
  time_variable = "age",
  disAge_variable = NULL,
  continuous_vars = NULL,
  categorical_vars = NULL,
  offset_vars = NULL,
  variance_mask = TRUE,
  N_trials = NULL,
  skip_gen_quant = FALSE,
  verbose = FALSE
)
```

Arguments

formula   A formula of the form y ~ x1 + x2 + x3 defining the response variable y and
                 covariates xi. The formula must contain exatly one tilde (~), with response
                 variable on the left-hand side and covariates on the right-hand side. Covariates
                 should be separated by a plus (+) sign. All variables that appear in the formula
                 must exist as columns of data. Note that effects of categorical covariates are by
                 default defined as interactions with time_variable. If you wish to change this,
                 see the argument offset_vars. The subject identifier variable cannot currently
                 be included in offset_vars. If you wish to model the effect of id_variable
                 as a constant offset, you can create another covariate with the same values and
                 use it in your formula and offset_vars instead.

data   A data frame containing the variables given in formula as columns.

likelihood   Determines the observation model. Must be either "Gaussian" (default), "Poisson",
                 "NB" (negative binomial) or "binomial". To use Bernoulli likelihood, use
                 likelihood="binomial" and set N_trials as a vector of ones.

prior   A named list, defining the prior distribution of model (hyper)parameters. It is
                 recommended to first create this using the function prior_default, and then
                 possibly modify it.

uncertain_effect_time

> Do we wish to model uncertainty in the disease effect time?

equal_effect   Is the disease effect assumed to be equally strong for all diseased individuals?

C_hat   The GP mean. Must be a vector of length dim(data)[1], or a real number defining a constant GP mean. If NULL, this is set to

- C_hat = 0, if likelihood is "Gaussian", because with Gaussian likelihood the response variable is by default centered to have zero mean.
- C_hat = log(mean(y)) if likelihood is "Poisson" or "NB",
- C_hat = log(p/(1-p)), where p = mean(y/N_trials) if likelihood is "binomial",

> where y denotes the response variable. You can modify this vector to account for normalization between data points. With Gaussian likelihood though, do not modify this argument, normalize the data beforehand instead.

DELTA   the amount of added jitter to ensure positive definiteness of the kernel

sample_F   Determines if the function values are be sampled (must be TRUE if likelihood is not "Gaussian").

id_variable   Name of the unique subject identifier variable (default = "id").

time_variable   Name of the time variable (default = "age").

disAge_variable

> Name of the disease-related age variable. If NULL, this will be chosen to be "diseaseAge", if such covariate is found in the data.

continuous_vars

> Names of other continuous covariates. If NULL, the remaining covariates that have floating point values are interpreted as continuous.

categorical_vars

> Names of categorical covariates that interact with the time variable. If NULL (default), the remaining covariates that have integer values are interpreted as categorical.

offset_vars   Names of the categorical covariates that are treated as time-independent group offsets. If NULL (default), no variables are interpreted as such covariates.

variance_mask   Should a variance mask be used to force disease component variance to zero before disease onset?

N_trials   This argument (number of trials) is only needed when likelihood is binomial. Must have length one or equal to number of data points. Setting N_trials=1 corresponds to Bernoulli observation model.

skip_gen_quant   If this is true, the generated quantities block of Stan is skipped.

verbose   Should more verbose output be printed?

Value

An object of class lgpmodel.

See Also

For fitting the model, see `lgp_fit`.

---

lgp_predict   *Compute predictions for a fitted model*

Description

Compute predictions for a fitted model. Only possible for models with Gaussian likelihood.

Usage

```
lgp_predict(
  fit,
  X_test,
  samples = "map",
  print_progress = TRUE,
  print_params = FALSE
)
```

Arguments

fit	An object of class lgpfit.
X_test	The test points where the predictions should be computed.
samples	The predictions can be computed either by using only the posterior mean (samples="mean"), median (samples="median"), or MAP (samples="map") parameters, or for all parameter samples (samples="all"). This can also be a set of indices, for example samples=c(1:10) gives predictions for the parameter samples 1...10.
print_progress	Should progress be printed (if there is more than one sample)?
print_params	Should the parameter values be printed? (only works if samples is mean or median.)

Value

A list.

See Also

- For creating an lgpfit object, see `lgp_fit`.

- For creating an lgpmodel object, see `lgp_model`.

---

lgp_test   *Compute predictions and log-posterior predictive density at test points*

Description

This is a convenience function that wraps `lgp_predict`, `compute_lppd` and `plot_posterior_y`.

Usage

```
lgp_test(fit, test_data, plot = FALSE, verbose = TRUE, samples = "mean")
```

Arguments

fit	an object of class `lgpfit`
test_data	a test data matrix
plot	should this return also a plot of the data and predictions?
verbose	Should this print progress?
samples	Sample indices or a keyword "mean", "median", "map", or "all".

Value

a ggplot object or lppd

---

likelihood_as_int   *Convert likelihood string to Stan encoding*

Description

Convert likelihood string to Stan encoding

Usage

```
likelihood_as_int(likelihood)
```

Arguments

likelihood	a string

Value

an integer

---

likelihood_as_str   *Convert the Stan likelihood encoding to a string*

Description

Convert the Stan likelihood encoding to a string

Usage

```
likelihood_as_str(LH)
```

Arguments

LH   an integer

Value

a string

---

log_gaussian_density   *Compute log-density for gaussian distribution*

Description

Compute log-density for gaussian distribution

Usage

```
log_gaussian_density(x, mu, s2)
```

Arguments

x   point x

mu   mean

s2   variance

Value

a number

---

matrix_to_df   *Matrix to data frame without editing column names*

Description

Matrix to data frame without editing column names

Usage

```
matrix_to_df(M)
```

Arguments

M   a matrix

Value

a data frame

---

model_info   *Get model info*

Description

Get model info

Usage

```
model_info(object, print = TRUE)
```

Arguments

object   an object of class lgpmodel or lgpfit

print   should this print the info?

Value

the info as a string

---

nameComponents   *Create names for all components based on covariate names and types*

Description

Create names for all components based on covariate names and types

Usage

```
nameComponents(types, names)
```

Arguments

types	vector of covariate types
names	names of the covariates

Value

a vector of component names

---

onsetsToDiseaseAge   *Compute the disease-related ages*

Description

Compute the disease-related ages

Usage

```
onsetsToDiseaseAge(onsets, age, k)
```

Arguments

onsets	true disease effect times, a vector of length N
age	the age covariate, a vector of length N*k
k	number of measurements per individual

Value

the diseaseAge covariate, a vector of length N*k

parse_prior_distribution

> *Turn a list describing a prior distribution into vectors to be given to Stan*

Description

Turn a list describing a prior distribution into vectors to be given to Stan

Usage

```
parse_prior_distribution(dist, add_correct = NULL)
```

Arguments

dist	a list with field type, and possibly others
add_correct	additional correct parameter names

Value

a list with two vectors to be given to Stan

parse_prior_t_effect   *Turn a list describing an effect time distribution into things to be given to Stan*

Description

Turn a list describing an effect time distribution into things to be given to Stan

Usage

```
parse_prior_t_effect(dist, N_cases, T_observed, T_last, UNCRT)
```

Arguments

dist	This is prior$effect, where prior is an argument of lgp_model
N_cases	number of case individuals
T_observed	observed disease onsets / initiation times
T_last	last time point for each diseased individual
UNCRT	0 or 1

Value

a list with things to be given to Stan

---

plot,lgpfit,ANY-method
Visualize a fitted 'lgpfit' object

Description

Visualize a fitted 'lgpfit' object

Usage

```
## S4 method for signature 'lgpfit,ANY'
plot(fit, x = 1, y = 1, color_scheme = "red")
```

Arguments

fit	an object of class lgpfit
x	does nothing
y	does nothing
color_scheme	bayesplot color scheme

Value

a ggplot object

---

plot_beta   *Visualize posterior samples of individual-specific disease effect magnitude parameters*

Description

Can only be used if the disease effect was modeled heterogeneously.

Usage

```
plot_beta(fit, color_scheme = "red", threshold = 0.5)
```

Arguments

fit	An object of class lgpfit.
color_scheme	Name of bayesplot color scheme.
threshold	Threshold for median.

Value

a ggplot object

Description

Helper function for plotting one component

Usage

```
plot_component(
  MMM,
  SSS,
  model,
  idx,
  time_is_xvar,
  linealpha,
  linetype,
  fill_alpha,
  X_test,
  marker,
  sum_highlight,
  viridis_option
)
```

Arguments

MMM	a n array of size n_samples x n_data x n_components
SSS	a n array of size n_samples x n_data x n_components
model	an object of class 'lgpmodel'
idx	Index of component to be plotted.
time_is_xvar	is the time variable the x-axis variable
linealpha	line alpha
linetype	line type
fill_alpha	fill alpha for geom_ribbons
X_test	optional matrix of test points
marker	point type
sum_highlight	name of a categorical covariate to be highlighted
viridis_option	the option argument of `ggplot2::scale_colour_viridis_c` by colour in the sum plot

Value

a ggplot object

---

plot_components *Helper function for plotting components*

Description

Helper function for plotting components

Usage

```
plot_components(
  MMM,
  SSS,
  model,
  time_is_xvar,
  X_test = NULL,
  sum_highlight = NULL,
  linealpha = 1,
  linetype = 1,
  fill_alpha = 0.3,
  marker = NULL,
  ncol = NULL,
  nrow = NULL,
  legend = NULL,
  labels = NULL,
  ylim = NULL,
  font_size = 9,
  theme = ggplot2::theme_linedraw(),
  legend_dir = "horizontal",
  xlabel = NULL,
  ylabel = " ",
  viridis_option = "viridis",
  return_list = FALSE
)
```

Arguments

MMM	a n array of size n_samples x n_data x n_components
SSS	a n array of size n_samples x n_data x n_components
model	an object of class 'lgpmodel'
time_is_xvar	is the time variable the x-axis variable
X_test	optional matrix of test points
sum_highlight	name of a categorical covariate to be highlighted
linealpha	line alpha
linetype	line type
fill_alpha	fill alpha for geom_ribbons
marker	point type
ncol	number of plot columns
nrow	number of plot rows

legend	legend argument for ggarrange, use "none" to remove legends
labels	labels argument for ggarrange
ylim	y axis limits
font_size	font size for plots
theme	ggplot theme
legend_dir	direction of legend
xlabel	x-axis label
ylabel	y-axis label
viridis_option	the option argument of ggplot2::scale_colour_viridis_c by colour in the sum plot
return_list	should this return a list of ggplot objects instead of doing ggarrange

Value

an object returned by ggpubr::ggarrange or list

---

plot_components_posterior

Visualize inferred components

Description

Visualize inferred components

Usage

```
plot_components_posterior(
  fit,
  subsamples = NULL,
  time_is_xvar = TRUE,
  PRED = NULL,
  marker = NULL,
  sample_idx = 1,
  n_sd = 2,
  ...
)
```

Arguments

fit	An object of class lgpfit.
subsamples	How many samples to plot. If this is NULL, average over all samples is plotted. If this is "all", all samples are plotted.
time_is_xvar	is the time variable the x-axis variable in all subplots?
PRED	object returned by lgp_predict
marker	point type
sample_idx	Which sample to plot.
n_sd	number of standard deviations (ribbon width)
...	additional arguments for plot_components

Value

an object returned by ggpubr::ggarrange or a list of ggplot2 objects

---

plot_components_posterior_sub1

Helper for `plot_components_posterior`

Description

Helper for `plot_components_posterior`

Usage

```
plot_components_posterior_sub1(fit, subsamples, time_is_xvar, marker, ...)
```

Arguments

fit	An object of class `lgpfit`.
subsamples	How many samples to plot. If this is NULL, average over all samples is plotted. If this is "all", all samples are plotted.
time_is_xvar	is the time variable the x-axis variable in all subplots?
marker	point type
...	additional arguments for `plot_components`

Value

an object returned by ggpubr::ggarrange or a list

---

plot_components_posterior_sub2

Helper for `plot_components_posterior`

Description

Helper for `plot_components_posterior`

Usage

```
plot_components_posterior_sub2(fit, PRED, sample_idx, time_is_xvar, n_sd, ...)
```

Arguments

fit	An object of class `lgpfit`.
PRED	object returned by `lgp_predict`
sample_idx	Which sample to plot.
time_is_xvar	is the time variable the x-axis variable in all subplots?
n_sd	number of standard deviations (ribbon width)
...	additional arguments for `plot_components`

Value

an object returned by ggpubr::ggarrange or a list

```
plot_components_simdata
```
Visualize the components of a simulated data set

Description

Visualize the components of a simulated data set

Usage

```
plot_components_simdata(simData, time_is_xvar = TRUE, marker = 16, ...)
```

Arguments

simData	simulated data object (list)
time_is_xvar	is the time variable the x-axis variable in all subplots?
marker	point marker
...	additional arguments for plot_components

Value

an object returned by ggpubr::ggarrange or list

```
plot_data                    A spaghetti plot of longitudinal data.
```

Description

A spaghetti plot of longitudinal data.

Usage

```
plot_data(
  data,
  highlight = NULL,
  response = "y",
  id_variable = "id",
  time_variable = "age",
  psize = 2,
  lwd = 0.5,
  title = NULL
)
```

Arguments

`data`	A data frame.
`highlight`	Name of a covariate to be highlighted with color, or id of a subject to be highlighted.
`response`	Name of the response variable.
`id_variable`	Name of id variable.
`time_variable`	Name of time variable.
`psize`	point size
`lwd`	line width
`title`	additional string added to title

Value

a ggplot object

`plot_data_hl_cat`	*A spaghetti plot of longitudinal data, highlighting a categorical covariate.*

Description

A spaghetti plot of longitudinal data, highlighting a categorical covariate.

Usage

```
plot_data_hl_cat(
  data,
  highlight = NULL,
  response = "y",
  id_variable = "id",
  time_variable = "age",
  psize = 2,
  lwd = 0.5
)
```

Arguments

`data`	A data frame.
`highlight`	Name of a categorical covariate to be highlighted with color.
`response`	Name of the response variable.
`id_variable`	Name of id variable.
`time_variable`	Name of time variable.
`psize`	point size
`lwd`	line width

Value

a ggplot object

plot_data_hl_cont	*A spaghetti plot of longitudinal data, highlighting a continuous covariate.*

Description

A spaghetti plot of longitudinal data, highlighting a continuous covariate.

Usage

```
plot_data_hl_cont(
  data,
  highlight = NULL,
  response = "y",
  id_variable = "id",
  time_variable = "age",
  psize = 2,
  lwd = 0.5,
  colgrad = ggplot2::scale_colour_gradient2()
)
```

Arguments

data	A data frame.
highlight	Name of a continuous covariate to be highlighted with color.
response	Name of the response variable.
id_variable	Name of id variable.
time_variable	Name of time variable.
psize	point size
lwd	line width
colgrad	color gradient

Value

a ggplot object

plot_data_hl_disease	*A spaghetti plot of longitudinal data, highlighting based on disease group.*

Description

A spaghetti plot of longitudinal data, highlighting based on disease group.

Usage

```
plot_data_hl_disease(
  data,
  highlight = "diseaseAge",
  response = "y",
  id_variable = "id",
  time_variable = "age",
  psize = 2,
  lwd = 0.5
)
```

Arguments

data	A data frame.
highlight	Name of the disease-related age variable.
response	Name of the response variable.
id_variable	Name of id variable.
time_variable	Name of time variable.
psize	point size
lwd	line width

Value

a ggplot object

---

plot_data_hl_individual

A spaghetti plot of longitudinal data, highlighting one individual.

Description

A spaghetti plot of longitudinal data, highlighting one individual.

Usage

```
plot_data_hl_individual(
  data,
  highlight = 1,
  response = "y",
  id_variable = "id",
  time_variable = "age",
  psize = 2,
  lwd = 0.5
)
```

Arguments

data	A data frame.
highlight	Number indicating the individual to highlight.
response	Name of the response variable.
id_variable	Name of id variable.
time_variable	Name of time variable.
psize	point size
lwd	line width

Value

a ggplot object

---

plot_data_plain	*A spaghetti plot of longitudinal data without highlighting.*

Description

A spaghetti plot of longitudinal data without highlighting.

Usage

```
plot_data_plain(
  data,
  response = "y",
  id_variable = "id",
  time_variable = "age",
  psize = 2,
  lwd = 0.5
)
```

Arguments

data	A data frame.
response	Name of the response variable.
id_variable	Name of id variable.
time_variable	Name of time variable.
psize	point size
lwd	line width

Value

a ggplot object

---

plot_effect_times   *Visualize posterior uncertainty in the disease effect times*

Description

Can only be used if the uncertainty of effect time was modeled.

Usage

```
plot_effect_times(
  fit,
  color_scheme = "red",
  prob = 1,
  prob_outer = 1,
  point_est = "none"
)
```

Arguments

fit	An object of class lgpfit.
color_scheme	Name of bayesplot color scheme.
prob	Inner interval
prob_outer	Outer interval
point_est	Point estimate type

Value

a ggplot object

---

plot_inputwarp   *Visualize the input warping function for different parameter samples*

Description

Visualize the input warping function for different parameter samples

Usage

```
plot_inputwarp(fit, p = 300, color_scheme = "red", b = 0, c = 1)
```

Arguments

fit	An object of class lgpfit.
p	number of plot points
color_scheme	Name of bayesplot color scheme.
b	location of the effective time window (default = 0)
c	maximum range (default = 1)

Value

a ggplot object

---

plot_posterior_f *Plot posterior of f*

Description

This is a wrapper for `plot_posterior_predictions`.

Usage

```
plot_posterior_f(
  fit,
  PRED = NULL,
  plot_uncertainty = TRUE,
  data_marker = 16,
  n_sds = 2,
  ...
)
```

Arguments

fit	An object of class `lgpfit`.
PRED	Predictions computed using `lgp_predict`.
plot_uncertainty	
	Should an uncertainty ribbon be plotted?
data_marker	pch for data points
n_sds	number of standard deviations for the uncertainty band width
...	additional arguments to `plot_posterior_predictions`

Value

a ggplot object

---

plot_posterior_predictions

Plot posterior of f or predictive distribution for y

Description

Plot posterior of f or predictive distribution for y

Usage

```
plot_posterior_predictions(
  fit,
  mode,
  PRED = NULL,
  color_scheme = "red",
  color_scheme_t_effect = "gray",
  alpha = 0.5,
  alpha_line = 1,
  alpha2 = 0.5,
  plot_uncertainty = TRUE,
  title = NULL,
  ylim = NULL,
  plot_obs_onset = FALSE,
  plot_t_effect_samples = FALSE,
  ypos_dens = NULL,
  test_data = NULL,
  color_test = "deepskyblue2",
  pch_test = 21,
  size_test = 2,
  error_bar = FALSE,
  n_sds = 2,
  reference_times = NULL,
  post_t_effect_stat = "none",
  original_y_scale = TRUE,
  data_color = "black",
  data_marker = 21,
  ons_linetypes = c(1, 2, 3),
  ons_linecolors = c("black", "red", "gray50")
)
```

Arguments

`fit`	An object of class `lgpfit`.
`mode`	Must be either "posterior" or "predictive".
`PRED`	Predictions computed using `lgp_predict`.
`color_scheme`	Name of bayesplot color scheme or a list with fieds 'dark' and 'light'.
`color_scheme_t_effect`	
	color scheme name for effect time density plotting
`alpha`	Ribbon fill opacity.
`alpha_line`	Line opacity.
`alpha2`	alpha of t_onset density
`plot_uncertainty`	
	Should an uncertainty ribbon be plotted?
`title`	optional prefix to plot title
`ylim`	y axis limits
`plot_obs_onset`	should the observed disease onset/initiation time be plotted by a vertical line
`plot_t_effect_samples`	
	should a distribution of sampled effect times be plotted

ypos_dens	y-position of the density plot
test_data	Test data frame
color_test	test point color
pch_test	test point marker
size_test	test point size
error_bar	should uncertainty be plotted using error bars instead of a ribbon
n_sds	number of standard deviations for the uncertainty band width
reference_times	
	reference onset times
post_t_effect_stat	
	statistic computed from effect time samples (mean or median)
original_y_scale	
	should the predictions be scaled back to original data scale
data_color	data marker color
data_marker	data marker type
ons_linetypes	onset line types
ons_linecolors	onset line colors

Value

a ggplot object

---

plot_posterior_y *Plot posterior predictive distribution*

Description

This is a wrapper for `plot_posterior_predictions`.

Usage

```
plot_posterior_y(
  fit,
  PRED,
  uncertainty = "ribbon",
  test_data = NULL,
  data_marker = 16,
  n_sds = 2,
  ...
)
```

Arguments

fit	An object of class `lgpfit`.
PRED	Predictions computed using `lgp_predict`.
uncertainty	Either "none", "ribbon" or "errorbar".
test_data	Test data set.
data_marker	pch for data points
n_sds	number of standard deviations for the uncertainty band width
...	additional arguments to `plot_posterior_predictions`

Value

a ggplot object

---

plot_predictions_add_onsets

Add disease onset / effect times to predictions plot

Description

NOTE: currently assumes that diseased individuals come first.

Usage

```
plot_predictions_add_onsets(
  fit,
  h,
  plot_obs_onset,
  plot_t_effect_samples,
  idvar,
  timevar,
  ypos_dens,
  color_scheme_t_effect,
  reference_times,
  post_t_effect_stat,
  linetypes = c(1, 2, 3),
  linecolors = c("black", "red", "gray50"),
  alpha2 = 1
)
```

Arguments

fit	An object of class `lgpfit`.
h	a ggplot object
plot_obs_onset	a boolean value
plot_t_effect_samples	
	a boolean value
idvar	id variable name
timevar	time variable name
ypos_dens	y position of the estimated onset density
color_scheme_t_effect	
	color scheme
reference_times	
	reference onset times
post_t_effect_stat	
	statistic computed from effect time samples
linetypes	onset line types
linecolors	onset line colors
alpha2	alpha parameter

Value

a modified ggplot object

---

plot_predictions_options
Do input checks and set options for plotting predictions

Description

Do input checks and set options for plotting predictions

Usage

```
plot_predictions_options(
  fit,
  color_scheme,
  original_y_scale,
  PRED,
  test_data,
  color_scheme_t_effect,
  mode,
  n_sds
)
```

Arguments

`fit`	An object of class `lgpfit`.
`color_scheme`	Name of bayesplot color scheme.
`original_y_scale`	Boolean value.
`PRED`	Predictions computed using `lgp_predict`.
`test_data`	test data
`color_scheme_t_effect`	Another color scheme.
`mode`	mode
`n_sds`	number of standard deviations for the uncertainty band width

Value

a list

---

plot_relevances   *Barplot of covariate relevances*

Description

Barplot of covariate relevances

Usage

```
plot_relevances(object, violin = FALSE, color_scheme = "red", ...)
```

Arguments

object	an object of class `lgpfit`
violin	Should a violin plot be used instead of a boxplot
color_scheme	bayesplot color scheme name
...	Additional arguments to `ggplot2::geom_boxplot` or `ggplot2::geom_violin`.

Value

a ggplot object

---

plot_samples   *Visualize the distribution of the model parameter samples*

Description

This is a wrapper for functions in the `bayesplot` package.

Usage

```
plot_samples(
  object,
  pars = character(),
  regex_pars = character(),
  type = "intervals",
  prob = 0.5,
  prob_outer = 0.9,
  color_scheme = "red",
  point_est = "median",
  binwidth = NULL,
  transformations = list(),
  off_diag_args = list(size = 1),
  facet_args = list()
)
```

Arguments

`object`	An object of class `lgpfit`.
`pars`	parameter names
`regex_pars`	regex for parameter names
`type`	Visualization type. Must be either `"dens"`, `"areas"`, `"intervals"`(default) or `"hist"`.
`prob`	inner interval
`prob_outer`	outer interval
`color_scheme`	See different color schemes in the `bayesplot` package.
`point_est`	the point estimate type
`binwidth`	width of histogram bins if `type = "hist"`
`transformations`	
	the parameter transformations
`off_diag_args`	Additional argument list for the pairs plot.
`facet_args`	additional facetting arguments

Value

a ggplot object

`plot_simdata`	*Plot a simulated longitudinal data set for each individual separately*

Description

Plot a simulated longitudinal data set for each individual separately

Usage

```
plot_simdata(
  simData,
  linecolor = "gray50",
  nrow = NULL,
  ncol = NULL,
  i_test = NULL,
  color_point = "black",
  color_test = "steelblue2",
  signal_name = "signal",
  y_transform = function(x) {     x }
)
```

Arguments

simData	a list returned by simulate_data
linecolor	line color
nrow	an argument for ggplot2::facet_wrap
ncol	an argument for ggplot2::facet_wrap
i_test	test point indices
color_point	data point color
color_test	test point color
signal_name	name of signal
y_transform	function to transform the data y

Value

a ggplot object

See Also

For plotting each component separately, see plot_components_simdata

---

postproc	*Finalize the lgpfit object after sampling*

Description

Finalize the lgpfit object after sampling

Usage

```
postproc(fit, threshold = 0.95, relevance_method = "f_mean", verbose = FALSE)
```

Arguments

fit	An (incomplete) object of class lgpfit.
threshold	Threshold for relevance sum. Must be a value between 0 and 1.
relevance_method	
	Component relevance determination method. Must be either "f_mean" or "alpha".
verbose	Should some output be printed?

Value

An updated object of class lgpfit.

---

postproc_relevances *Compute component relevances and estimate amount of noise (one MCMC sample)*

Description

Compute component relevances and estimate amount of noise (one MCMC sample)

Usage

```
postproc_relevances(
  fit,
  relevance_method = "f_mean",
  noise_method = "SSE",
  verbose = FALSE
)
```

Arguments

fit	An (incomplete) object of class lgpfit.
relevance_method	
	Component relevance determination method. Must be either "f_mean" or "alpha".
noise_method	Noise level determination method. Currently must be "SSE".
verbose	Should some output be printed?

Value

An updated object of class lgpfit.

---

predict_preproc *Preprocess some things before computing predictions*

Description

This is a helper function for [lgp_predict](#).

Usage

```
predict_preproc(fit, X_test, samples)
```

Arguments

fit	An object of class lgpfit.
X_test	The test points where the predictions should be computed.
samples	The samples argument to [lgp_predict](#)

PRED_to_arrays   *PRED object to arrays*

Description

PRED object to arrays

Usage

```
PRED_to_arrays(PRED)
```

Arguments

PRED   an object returned by `lgp_predict`

Value

a list containing two arrays

---

print_prior   *Human-readable description of a specified prior*

Description

Print human-readable info about the prior specification that was used or will be used

Usage

```
print_prior(object)
```

Arguments

object   An object of class `lgpfit` or a valid prior argument for the 'lgp' function.

Value

nothing

---

prior_default *Create the default prior*

Description

Create the default prior

Usage

```
prior_default(sigma_alpha = 1)
```

Arguments

sigma_alpha   Sigma parameter of the student-t distribution for all alpha.

Value

A list defining a valid prior argument for the lgp function.

---

prior_LonGP *Create a similar default prior as in* LonGP *(Cheng et. al, 2019)*

Description

Not recommended, because a lengthscale close to 0 is possible.

Usage

```
prior_LonGP()
```

Value

A list defining a valid prior argument for the lgp_model function.

---

prior_stan_to_readable

Human-readable information about the priors in the Stan data object

---

Description

Human-readable information about the priors in the Stan data object

Usage

```
prior_stan_to_readable(stan_dat)
```

Arguments

stan_dat   The list that is passed as data to rstan::sampling.

Value

Info as a string.

---

prior_statement	*Human-readable prior statement*

Description

Human-readable prior statement

Usage

```
prior_statement(parname, TYP, P, dist, row_change = TRUE)
```

Arguments

parname	parameter name
TYP	two integers
P	three real numbers
dist	list of distribution names
row_change	should a newline be last character?

Value

Sampling statement as a string.

---

prior_to_stan	*Get priors as a format that can be input to Stan*

Description

Get priors as a format that can be input to Stan

Usage

```
prior_to_stan(D, prior, HMGNS, UNCRT, N_cases, T_observed, T_last)
```

Arguments

D	an integer vector of length 6
prior	The `prior` argument supplied to `lgp()`.
HMGNS	Is diseaseAge assumed to have a homogenous effect (1) or not (0)?
UNCRT	Boolean value, is uncertainty of disease onset modeled?
N_cases	number of case individuals
T_observed	observed disease onsets
T_last	last time point for each diseased individual

Value

a list with all things related to priors that Stan needs

---

repvec *Repeat a vector as a rows of an array*

Description

Repeat a vector as a rows of an array

Usage

```
repvec(v, n)
```

Arguments

v   a vector of length m

n   number of times to repeat

Value

returns an array of size n x m

---

rtgeom *Sample from the 'truncated geometric' distribution*

Description

Sample from the 'truncated geometric' distribution

Usage

```
rtgeom(s, p, n = 1)
```

Arguments

s   an integer

p   a number between 0 and 1

n   number of samples

Value

an integer from the interval 1...n

---

scaleRelevances   *Scale the effect sizes*

Description

Scale the effect sizes

Usage

```
scaleRelevances(FFF, relevances, force_zeromean, i_skip)
```

Arguments

FFF	matrix where one column corresponds to one additive data component
relevances	the desired variance of each component (column)
force_zeromean	Should each component (excluding the disease age component) be forced to have a zero mean.
i_skip	induces of components for which the zero-mean forcing is skipped

Value

a new matrix FFF

---

selection   *Selection of relevant components*

Description

Selection of relevant components

Usage

```
selection(object, threshold = 0.95)
```

Arguments

object	An object of class lgpfit.
threshold	Threshold for relevance sum. Must be a value between 0 and 1.

Value

A named list

```
selection_fixed_threshold
```
Select relevant components

Description

Select relevant components

Usage

```
selection_fixed_threshold(rel, threshold)
```

Arguments

`rel`	a named vector of component relevances
`threshold`	value between 0 and 1

Value

indices of selected components (including "noise" always)

```
selection_prob
```
Probabilistic selection of relevant components

Description

Probabilistic selection of relevant components

Usage

```
selection_prob(
  object,
  p = function(x) {     stats::dbeta(x, 100, 5) },
  h = 0.01,
  show_progbar = FALSE
)
```

Arguments

`object`	An object of class `lgpfit`.
`p`	a function defining a density over interval [0,1]
`h`	discretization parameter for computing a quadrature
`show_progbar`	Should this show a progress bar?

Value

Selection probabilities for each component

selection_prob_fixed_threshold

Selection probabilities using a fixed threshold

Description

Selection probabilities using a fixed threshold

Usage

```
selection_prob_fixed_threshold(relevances, threshold)
```

Arguments

relevances   The `relevances$samples` slot of an `lgpfit` object.

threshold   value between 0 and 1

Value

proportion of times each component was selected

selection_prob_plot   *Plot of probabilistic selection of relevant components*

Description

Plot of probabilistic selection of relevant components

Usage

```
selection_prob_plot(PROB, H, P)
```

Arguments

PROB   computed probabilities at points H

H   a grid on interval [0,1]

P   threshold probability distribution evaluated at H

Value

a ggplot object

---

set_C_hat *Set C_hat (Non-gaussian observation models)*

Description

Set C_hat (Non-gaussian observation models)

Usage

```
set_C_hat(C_hat, response, LH, N_trials)
```

Arguments

C_hat	the C_hat argument given as input to lgp_model
response	response variable
LH	likelihood as int
N_trials	the N_trials data (binomial likelihood)

Value

a real number

---

set_N_cat *Count numbers of different categories for each categorical variable*

Description

Count numbers of different categories for each categorical variable

Usage

```
set_N_cat(X, D)
```

Arguments

X	the design matrix
D	a vector of length 6

Value

a numeric vector

---

set_N_trials *Set N_trials (binomial and Bernoulli observation models)*

Description

Set N_trials (binomial and Bernoulli observation models)

Usage

```
set_N_trials(N_trials, response, LH)
```

Arguments

N_trials	the N_trials argument given as input to lgp_model
response	response variable
LH	likelihood as int

Value

a numeric vector

---

show,lgpfit-method *Show a summary of results of the* lgp *function*

Description

Show a summary of results of the lgp function

Usage

```
## S4 method for signature 'lgpfit'
show(object)
```

Arguments

object	an object of class lgpfit

Value

nothing

show,lgpmodel-method   *Show a summary of an* lgpmodel

Description

Show a summary of an lgpmodel

Usage

```
## S4 method for signature 'lgpmodel'
show(object)
```

Arguments

object   an object of class lgpmodel

Value

nothing

simdata_colnames_pretty
                 Simulated data column names in a prettier form

Description

Simulated data column names in a prettier form

Usage

```
simdata_colnames_pretty(cn)
```

Arguments

cn   column names

Value

names of model components

---

simulate_data   *Generate an artificial longitudinal data set*

Description

Generate an artificial longitudinal data set.

Usage

```
simulate_data(
  N,
  t_data,
  covariates = c(),
  names = NULL,
  relevances = c(1, 1, rep(1, length(covariates))),
  n_categs = rep(2, sum(covariates %in% c(2, 3))),
  t_jitter = 0,
  lengthscales = rep(12, 2 + sum(covariates %in% c(0, 1, 2))),
  f_var = 1,
  noise_type = "Gaussian",
  snr = 3,
  phi = 1,
  N_affected = round(N/2),
  t_effect_range = "auto",
  t_observed = "after_0",
  C_hat = 0,
  dis_fun = "gp_vm",
  bin_kernel = FALSE,
  steepness = 0.5,
  vm_params = c(0.025, 1),
  continuous_info = list(mu = c(pi/8, pi, -0.5), lambda = c(pi/8, pi, 1)),
  N_trials = 1,
  verbose = FALSE,
  force_zeromean = TRUE
)
```

Arguments

N	Number of individuals.
t_data	Measurement times.
covariates	Integer vector that defines the types of covariates (other than id and age). If not given, only the id and age covariates are created. Different integers correspond to the following covariate types:

- 0 = disease-related age
- 1 = other continuous covariate
- 2 = a categorical covariate that interacts with age
- 3 = a categorical covariate that acts as a group offset
- 4 = a categorical covariate that that acts as a group offset AND is restricted to have value 0 for controls and 1 for cases

names	Covariate names.
relevances	Relative relevance of each component. Must have be a vector so that `length(relevances) = 2 + length(covariates)`. First two values define the relevance of the infividual-specific age and shared age component, respectively.
n_categs	An integer vector defining the number of categories for each categorical covariate, so that `length(n_categs)` equals to the number of 2's and 3's in the `covariates` vector.
t_jitter	Standard deviation of the jitter added to the given measurement times.
lengthscales	A vector so that `length(lengthscales) = 2 + sum(covariates %in% c(0,1,2))`.
f_var	variance of f
noise_type	Either "Gaussian", "Poisson", NB" (negative binomial) or "binomial".
snr	The desired signal-to-noise ratio. This argument is valid only with `noise_type = "Gaussian"`.
phi	The dispersion parameter for negative binomial data. The variance is $g + g^2/phi$.
N_affected	Number of diseased individuals that are affected by the disease. This defaults to the number of diseased individuals. This argument can only be given if `covariates` contains a zero.
t_effect_range	Time interval from which the disease effect times are sampled uniformly. Alternatively, This can any function that returns the (possibly randomly generated) real disease effect time for one individual.
t_observed	Determines how the disease effect time is observed. This can be any function that takes the real disease effect time as an argument and returns the (possibly randomly generated) observed onset/initiation time. Alternatively, this can be a string of the form `"after_n"` or `"random_p"` or `"exact"`.
C_hat	A constant added to f
dis_fun	A function or a string that defines the disease effect. If this is a function, that function is used to generate the effect. If dis_fun is "gp_vm" or "gp_ns", the disease component is drawn from a nonstationary GP prior (vm is the variance masked version of it).
bin_kernel	Should the binary kernel be used for categorical covariates? If this is TRUE, the effect will exist only for group 1.
steepness	Steepness of the input warping function. This is only used if the disease component is in the model.
vm_params	Parameters of the variance mask function. This is only needed if useMaskedVarianceKernel = TRUE.
continuous_info	
	Info for generating continuous covariates. Must be a list containing fields `lambda` and `mu`, which have length 3. The continuous covariates are generated so that x `<-sin(a*t + b) + c`, where • `t <-seq(0,2*pi,length.out = k)` • `a <-mu[1] + lambda[1]*stats::runif(1)` • `b <-mu[2] + lambda[2]*stats::runif(1)` • `c <-mu[3] + lambda[3]*stats::runif(1)`
N_trials	The number of trials parameter for binomial data.
verbose	verbosity mode
force_zeromean	Should each component (excluding the disease age component) be forced to have a zero mean?

Value

A list out, where

- `out$data` is a data frame containing the actual data and
- `out$components` contains more points for smoother visualizations of the generating process.
- `out$onsets` contains the real disease effect times
- `out$p_signal` proportion of variance explained by signal

Examples

```
# Generate Gaussian data
dat <- simulate_data(N = 4, t_data = c(6,12,24,36,48), snr = 3)

# Generate negative binomially distributed count data
dat <- simulate_data(N = 6, t_data = seq(2, 10, by = 2), noise_type = "NB", phi = 2)
```

---

simulate_kernels   *Compute all kernel matrices when simulating data*

Description

Compute all kernel matrices when simulating data

Usage

```
simulate_kernels(
  X,
  types,
  lengthscales,
  X_affected,
  bin_kernel,
  useMaskedVarianceKernel,
  steepness,
  vm_params
)
```

Arguments

X	covariates
types	vector of covariate types, so that

- 1 = ID
- 2 = age
- 3 = diseaseAge
- 4 = other continuous covariate
- 5 = a categorical covariate that interacts with age
- 6 = a categorical covariate that acts as an offset

lengthscales	vector of lengthscales
X_affected	which individuals are affected by the disease

bin_kernel	whether or not binary (mask) kernel should be used for categorical covariates
useMaskedVarianceKernel	
	should the masked variance kernel be used for drawing the disease component
steepness	steepness of the input warping function
vm_params	parameters of the variance mask function

Value

a 3D array

---

sim_check_covariates   *Input check for the covariates-related arguments of* simulate_data

---

Description

Input check for the covariates-related arguments of simulate_data

Usage

```
sim_check_covariates(covariates, relevances, names, n_cat)
```

Arguments

covariates	argument to simulate_data
relevances	argument to simulate_data
names	argument to simulate_data
n_cat	the n_categs argument to simulate_data

Value

the covariate names

---

sim_data_to_observed   *Real generated disease ages to observed ones*

Description

Real generated disease ages to observed ones

Usage

```
sim_data_to_observed(dat, t_observed)
```

Arguments

| dat | data frame |
| t_observed | Determines how the disease onset is observed. See documentation of [simulate_data](#). |

Value

a new data frame and observed onsets

sim_generate_names   *Generate names for covariates*

Description

Generate names for covariates

Usage

```
sim_generate_names(covariates)
```

Arguments

covariates   vector of covariate types

Value

covariate names

sim_parse_t_obs   *Parse the t_observed argument of* `simulate_data`

Description

Parse the t_observed argument of `simulate_data`

Usage

```
sim_parse_t_obs(t_observed)
```

Arguments

t_observed   a string

Value

a list with a name and number

---

split_data   *Split data into training and test data according to given row indices*

Description

Split data into training and test data according to given row indices

Usage

```
split_data(data, i_test, sort_ids = TRUE)
```

Arguments

data	a data frame
i_test	test data row indices
sort_ids	should the test indices be sorted into increasing order

Value

a list(train,test)

---

split_data_by_id   *Split data into training and test data according to given individuals*

Description

Split data into training and test data according to given individuals

Usage

```
split_data_by_id(data, test_ids, id_variable = "id")
```

Arguments

data	a data frame
test_ids	test data individual identifiers
id_variable	name of id variable

Value

a list(train,test)

---

split_data_by_timepoint

Split data into training and test data according to time point indices

---

Description

Split data into training and test data according to time point indices

Usage

```
split_data_by_timepoint(
  data,
  test_idx,
  id_variable = "id",
  time_variable = "age"
)
```

Arguments

data	a data frame
test_idx	indices of test time points
id_variable	name of id variable
time_variable	name of time variable

Value

a list(train,test)

---

split_data_random   *Split data into training and test data randomly*

Description

Split data into training and test data randomly

Usage

```
split_data_random(data, p_test = 0.1, n_test = NULL)
```

Arguments

data	a data frame
p_test	desired proportion of test data
n_test	desired number of test data points (if NULL, p_test is used to compute this)

Value

a list(train,test)

split_data_random_each

Split data into training and test data by selecting randomly k points from each individual

Description

Split data into training and test data by selecting randomly k points from each individual

Usage

```
split_data_random_each(
  data,
  n_test = 1,
  id_variable = "id",
  time_variable = "age"
)
```

Arguments

data	a data frame
n_test	desired number of test data points per individual
id_variable	name of id variable
time_variable	name of time variable

Value

a list(train,test)

---

standardize_inputs   *Standardize continuous input variables in X*

Description

Standardize continuous input variables in X

Usage

```
standardize_inputs(X, D)
```

Arguments

X	the design matrix
D	the covariate types, a vector of length 6

Value

updated X and info about scaling

---

stan_input_X_and_D   *Predictor covariates and types to Stan input*

Description

Reorders covariates and takes only those that are needed

Usage

```
stan_input_X_and_D(data, varInfo, types, formula, verbose)
```

Arguments

data	a data frame containing the covariates
varInfo	original variable type info
types	types of the covariates
formula	model formula
verbose	can this print some info?

Value

X and needed types and updated varInfo

---

validate_prior   *Validate prior by sampling the signal and noise from it*

Description

Validate prior by sampling the signal and noise from it

Usage

```
validate_prior(model, chains = 4, iter = 1000, parallel = FALSE)
```

Arguments

model	An object of class [lgpmodel]().
chains	how many chains are used to sample from the prior
iter	for how many iterations are the chains run
parallel	should the chains be run in parallel?

Value

An object of class `lgpfit` and random samples of both 'f' and 'y'.

---

var_mask *Variance masking function*

Description

Variance masking function

Usage

```
var_mask(x, a)
```

Arguments

x	vector of length n
a	a positive real number

Value

a vector of length n

---

warp_input *Input warping function*

Description

Input warping function

Usage

```
warp_input(t, a, b, c)
```

Arguments

t	a vector
a	steepness of the rise
b	location of the effective time window
c	maximum range

Value

a vector of warped inputs w(t)

Index
